

# Analysis of the causes of high temperature of photovoltaic panels

## Overview

Solar panels can overheat due to several reasons. One primary factor is their exposure to direct sunlight for extended periods, especially during peak sun hours. The negative effect of the operating temperature on the functioning of photovoltaic panels has become a significant issue in the actual energetic context and has been studied intensively during the last decade. They are made up of numerous solar cells, typically composed of silicon, which absorb photons from sunlight. Although numerous investigations have examined these stressors in themselves, this research addresses their interrelationship and evaluates. Solar panels are rated based on their performance at standard test conditions (STC), which include a temperature of 25°C. However, actual operating conditions often exceed this temperature, leading to a decrease in efficiency.
